Let's Start!

The Importance of Variables in PHP

```
public class VarDeclaration {  
  
    public static void main(String[] args) {  
        // TODO Auto-generated method stub  
        int id_number = 42781;  
        double pi_num = 3.142;  
        String print_string = "Hello, World";  
  
        System.out.println(id_number);  
        System.out.println(pi_num);  
        System.out.println(print_string);  
    }  
}
```

Learning Outcome:

Understand information about web applications, their principles and basic concepts in a range of work contexts.
Describe applications for an operating system for personal computers in a range of work contexts.

Can Do Statements:

- I can say what a variable in PHP is.
- I can present the rules of PHP variables.
- I can talk about the different variable scopes in PHP.

Ask your partner:

- What are the purposes of variables?
- Are variables created the same way in different programming languages?

Let's Explore!

Maria is checking if George understands the variables in PHP.

Instructions: Read the text below.

George: Mary, could you give me a hand, please?

Mary: Sure! But, you are making that variable wrong. The name of variables cannot be followed by numbers. Don't you remember that Mr. Williams told us that the sign \$ cannot be changed in the PHP variables?

George: Who?

Mary: The engineer, who came last week for the training session.

George: No. I wasn't there. What did he say?

Mary: First, variables are containers that help us to store data. A variable is created when you assign a value to a text. It's important to consider that variables work differently in each programming language. In this case, PHP doesn't have a command which can declare a variable. In addition, it's a must that all variables start with the \$ sign, and remember that variables are case-sensitive, too. We can put short names, just a letter works, but we can also set long names. Letters or numbers different from A-Z and 0-9 can't be used to create those names, right?

George: And, what about scopes?

Mary: Scopes are the parts of scripts, in which a variable is used or referenced. There are three scopes. Do you know them?

George: Yes, but I only understand two of them. Firstly, the global scope, which is used when a variable is declared outside a function. For this reason, it can't be accessed from within a function, only from the outside. Secondly, the local scope works the other way around. These scopes can only be accessed from within functions.

Mary: You've got it! The last one, static scope is used when you don't want the data to be deleted after the function is executed.

Let's Practice!

False Statements About Variables in PHP

Instructions: Match the sentences from Column A with Column B.

COLUMN A

1. Information cannot be
2. Variables cannot be considered
3. Variables
4. Variables in PHP can't be created
5. Variables in PHP cannot

COLUMN B

- a. converted automatically when declaring it.
- b. after assigning a value to it.
- c. can't be changed in other programming languages.
- d. as containers which store data.
- e. be included in any programming language.

Let's Practice!

What do you think about PHP variables?

Instructions: Select the correct category in the table. There is only one answer per category.

	It can be considered as a rule of PHP variables.	It cannot be consider as a rule of PHP variables.
Variables must start with \$, which is the representative sign.		
Variables can be designated with short labels that are easy to find.		
Variables can be also named with long labels, which provide more information about them.		
Letters or numbers different from A-Z and 0-9, which are used to create variables' names, vary according to the function.		
Programmers, who use variables, must know these are case-sensitive.		

Extension Activity

Declaring PHP Variables

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Look for more information about the scopes of PHP variables.
- Make a comparative chart in which you describe the three scopes (Global, Local, and Static scopes) of PHP variables, including examples.
- Share your chart with your instructor.

Self-Assessment

Yes

No

- I look for information about scopes.
- I make a comparative chart about scopes.
- I share my chart with the instructor.

☐	☐
☐	☐

Target Words

- **must** (noun): something that is necessary
e.g. In addition, it's a must that all variables start with the \$ sign.
- **scope** (noun): the range or extent of a variable
e.g. Scopes are the parts of scripts, in which a variable is used or referenced.
- **give a hand** (expression): to help someone
e.g. Mary, could you give me a hand, please?
- **declare** (verb): to announce; in programming, it refers to write codes
e.g. In this case, PHP doesn't have a command which can declare a variable.
- **case-sensitive** (adjective): related to the use of capital letters
e.g. Remember that variables are case-sensitive, too.

Learning Points

Passive of Modal Verbs: Can

We use the **passive voice** when we want to emphasize in the action and not in the person who does it.

Passive voice can be used anytime; we are going to focus on can and how to use it in negative sentences this time.

Can, in negative sentences, is used to refer to forbidden situations or facts that are not possible.

Look at the following structure:

Subject + **can't / cannot** + **be** + **verb in past participle** + complement

Examples:

*The cd room **can't be considered** as something modern anymore.*

*Variables **can't be followed** by numbers.*

Examples

- *The sign \$ cannot be changed in the PHP variables.*
- *The name of variables cannot be followed by numbers.*

Declaring Variables in PHP

There are rules to follow if you want to declare a variable in PHP.

To declare or create a variable in PHP, consider the following rules:

- Start with the sign \$; then, write the name of the variable.
- The name must start with a letter or underscore character, it can't start with a number.
- It can make use of the alpha-numeric characters and underscores.
- They are case-sensitive.

Examples:

\$txt

\$y

\$Y: this one is different from \$y because it is case sensitive,

\$total_volume
